Application Sandboxes

- Isolate general purpose applications
- Target specific use cases
- Variety of approaches
 - Seccomp - Linux syscall restriction
 - Java VM - bytecode verification
 - SELinux - MCS isolation
 - Virtualization - OS separation
- Multiple layers of defense

Linux Containers

- What is a container?
 - Most people think LXC
 - We will use libvirt-lxc rather than lxc command set.
 - Linux namespaces

Namespaces

- pam_namespace - RHEL5/Fedora 6
- SELinux sandbox - RHEL6/Fedora 8
- Systemd - Fedora 17
 - UnitFile: PrivateTmp, PrivateNetwork
- Openshift - RHEL6
 - Pam_namespace : Private /tmp

Linux Namespaces

- Mount : mounting/unmounting filesystems
- UTS : hostname, domainname
- IPC : SysV message queues, semaphore/shared memory segments
- Network: IPv4/IPv6 stacks, routing, firewall, proc/net /sys/class/net directory trees, sock
- Pid: Own set of pids
- UID: Not implemented yet.

libvirt

- Standard, simple, secure C API
- API bindings
 - Perl, Python, Java, etc
- Mapping to object models
 - SNMP, GObject, CIM, QMF
- Remote RPC access
 - SSH, TLS, GSSAPI

libvirt-lxc

- Container virtualization
- Boot “init” binary
- sVirt SELinux TE + MCS
- Firewall ebtables/ip[6]tables
- Host FS passthrough bind mounts
- CGroups resource control

libvirt-sandbox API

- Based on GObject object system
- Uses libvirt-`{glib,gconfig,gobject}`
- Accessible from non-C via introspection
- All CLI tools built on top of the API

Example: Server Virtual Hosting

- Goal:
 - Deploy multiple Apache virtual hosts
 - Strong isolation between virtual hosts
- Solution:
 - One apache instance per virtual host
 - Run apache inside a sandbox

virt-sandbox-service

- virt-sandbox-service create -C -u httpd.service apache1
 - Config /etc/libvirt-sandbox/service/apache1.sandbox
 - Multiple unit files allowed
 - SystemD unit file
 - /etc/systemd/system/httpd@apache1.service
 - Create state directories or image
 - /var/lib/libvirt/filesystem/apache1
 - Chroot type directory
 - Examines rpm payload
 - Clone - /var and /etc config
 - Share /usr

Allocate unique MCS security label

virt-sandbox-service

- virt-sandbox-service start apache1
 - Starts service from config
- virt-sandbox-service stop apache1
 - Stop service
- virt-sandbox-service connect apache1
 - Connect admin debug shell to container
- Virt-sandbox-service execute -C ifconfig apache1
 - Execute command within container
 - virt-sandbox-service.logrotate
 - /usr/bin/virt-sandbox-service execute -C /etc/cron.daily/logrotate \$i

Systemd

- `systemctl start httpd@apache1.service`
- `systemctl reload httpd.service`
 - Should trigger reload in all `httpd@` services
 - `ReloadPropagatedFrom=httpd.service`
- `Systemctl start httpd@.service`
 - Should start all `httpd` services

Other Use cases

- Run mock within a container
- Run customer services on gluster nodes
- Run mysql within a container
- OpenShift work loads

Demo

- `libvirt-0.10.0-0rc0.2.fc18.x86_64`
- `libvirt-sandbox-0.1.0-1.fc18.x86_64`
- `selinux-policy-3.11.1-7.fc18.noarch`
